ABSTRACT

Objective: The present investigations were undertaken to evaluate the hepatoprotective of the ethanolic extract of Indigofera tirunelvelica Sanjappa (Et-It) against CCl₄-induced hepatotoxicity in rats. Methods: Hepatoprotective effect of ethanolic extract of Indigofera tirunelvelica (EtL-It) was determined by using carbon tetrachloride (CCl₄) intoxication of rats as experimental models. The range of liver impairment and effect of the extract of medicinal plant was evaluated by assorted biochemical markers like aspartate aminotransferase (AST), alkaline phosphatase (ALP), alanine aminotransferase (ALT), total protein (TP) and total bilirubin (TB) in blood serum and concentration of Lipid peroxidation (LPO), superoxide dismutase (SOD), catalase (CAT), reduced glutathione (GSH), glutathione-s-transferase (GST) and glutathione peroxidase (GPx), in liver were determined. Histopathological changes in the liver of different groups were also studied. Results: The administration of Et-It at dose levels of 100, 200 and 400 mg/kg/b.w., orally had decreased the rise of ALT, AST, ALP, TB and TBRAS levels and the effects were comparable to standard drug (Silymarin 20 mg/kg/b. w,) the GSH, SOD, CAT, GPx, GST and TP levels were significantly increased in the animals received EtL-It. The histopathological studies show decreased necrosis and hepatocellular degeneration when compared to the CCl₄ intoxicated liver. Conclusion: This study demonstrates that the hepatoprotective of Indigofera tirunelvelica therefore scientifically supports the use of this plant in traditional medicine for treatment of liver disorders.

Indigofera tirunelvelica, Liver regeneration, CCl₄, Hepatoprotective

INTRODUCTION

The liver is the most important metabolic organ. The incessant exposure and a numerous toxic environmental agent, certain chemical drugs induce hepatic injury, identified as a toxicological problem [1]. Most of the toxic chemicals damage the liver cells mainly by inducing lipid peroxidation and other oxidative damages in liver [2]. The choice of treatment for common liver diseases such as cirrhosis, fatty liver, and chronic hepatitis is problematic [3]. In spite of amazing development in modern medicine no effective drugs are available, which activate liver functions and often protect the liver from the damage or helps to reconstruct hepatic cells [4]. In the lack of reliable liver protective drugs in modern medicine, Plants traditionally used in the relief of liver dysfunction might,
Studies were carried out using Wister albino male rats (150-200g), obtained from Biogen Pvt. Ltd., Hosur, Tamilnadu, India. The animals were grouped and housed in polyacrylic cages (38 x 23 x10 cm) with not more than six animals per cage and maintained under standard laboratory conditions (temperature 25±2°C) with dark and light cycle (12/12 h). The animals were fed with standard pellet diet supplied by the animal suppliers and fresh water ad libitum. All the animals were acclimatized to laboratory condition for a week before the commencement of the experiment. All animal studies were performed in accordance to guidelines of CPCSEA and Institutional Animal Ethical Committee (IAEC) of Srimad Andavan College of Arts and Science, Tiruchirappalli, Tamil Nadu. CPCSEA registration number was SAC/IAEC/BC/2016/Ph.D. - 004, and all the procedures were followed as per rules and regulation.

**Acute toxicity studies**

An acute oral toxicity study was performed as per OECD-423 guidelines (acute toxic class method), Albino rats (n=6) of single-sex were selected for the acute toxicity study. Which received a single oral dose of 5000 mg/kg body weight of EtL-It. The dose was administered to overnight fasted rats, and the food was withheld for a further 3-4 h after administration of the drug and observed for signs of toxicity for a period of 21 days [6].

**Experimental design**

**CCL4-induced hepatotoxicity study**

After acclimatization, the rats were divided into 6 groups of 6 rats each. Group I: Served as Normal control which received saline orally. Group II to V: Were administered orally with CCl4 (0.5 ml/150 g of bw v/v in olive oil on 1st, 8th and 16th days). Group III and IV: Were administrated with Et-It at the dose of 100, 200 and 400 mg/kg bw orally once in every 24 h for 21 days respectively. Group-V: Was administrated with reference drug Silymarin at the dose of 20 mg/kg bw orally once in every 24 h for 21 days [7].

**Estimation of biochemical parameters**

The biochemical parameters were determined after 24 h fasting of the last dose. Blood was obtained from all animals by puncturing retro- orbital plexus. The blood samples were allowed to clot for 45 min at room temperature. Serum was separated by centrifugation at 2500 RPM at 30 °C for 15 min and used for the estimation of various biochemical parameters namely alanine transaminase (ALT), aspartate transaminase...
AST), alkaline phosphatase (ALP) [8], total bilirubin (TB) [9] and total protein content (TP) [10]. The dissected liver was washed with 0.9% saline and homogenated (5%) in ice-cold phosphate buffer, and then centrifuged at 1000 RPM for 10 min followed by centrifugation of the supernatant at 12000 RPM for 15 min to get the mitochondrial fractions. These fractions were used for the estimations of thiobarbituric acid reactive substances (TBARS) [11]. Reduced glutathione (GSH) [12], superoxide dismutase (SOD) [13], catalase (CAT) [14], glutathione peroxidase (GPx) [15], glutathione-s-transferase (GST) [16].

**Statistical analysis**
The results are expressed as mean±SE of six animals from each group. One-way ANOVA followed by Dunnet multiple comparison tests have used to analyze the data. P<0.05 was considered statistically significant.

**Histopathological study**
After the collection of blood samples, the rats were sacrificed, and their livers were excised, rinsed in ice-cold normal saline and processed separately for histological observation. Initially, the materials were fixed at 10% buffered neutral formalin solution for 48 h and then with a bovine solution for 6 h. Paraffin sections were taken at 5 mm thickness processed in alcohol-xylene series and was stained with alum hematoxylin and eosin [17]. The sections were examined under photomicroscope for histopathological changes, necrosis, steatosis and fatty changes of hepatic cells.

**RESULTS**

**Acute toxicity**
It was observed that the administration of single oral dose 5000 mg/kg/body weight of ethanol extract of *Indigofera tirunelvelica* to a rat, didn't induce drug-related toxicity and mortality in the animals, and it was safe up to the dose of 5000 mg/kg/body weight.

**Biochemical parameters**
The effect of the Et-It of CCl₄ induced hepatotoxicity and oxidative stress in rats were represented in the fig. 1-5. The animals administrated only with CCl₄ resulted in a significant increase (P<0.05) in serum ALT, AST, ALP and TB levels as shown in the fig. 1-2. However, the total serum protein [TP] level was decreased when compared to a normal control group, indicating hepatocellular damage. The toxic effects of CCl₄ were controlled in the animals treated with Et-It at the doses of 100, 200 and 400 mg/kg b.w., produced significant (P<0.05) dose-dependent decreases in serum marker enzyme ALT, AST, ALP (fig. 1) and TB (fig. 2) respectively as well as increases total protein level (fig. 2) as compared with normal control by the way of restoration of the level of the liver function similar to that of the reference drug silymarin (20 mg/kg. b. w).

The activity of lipid peroxidation (LPO) level was significantly (P<0.05) increased (fig. 3) and GST, GPx, GSH (fig. 4), CAT and SOD activity were significantly (P<0.05) decreased (fig. 5) in the serum level of rats treated with CCl₄ when compared with that of the normal control that received only olive oil. Treatment of rats with Et-It at the dose of 100, 200 and 400 mg/kg b.w., significantly (P<0.05) decreased the elevated lipid peroxidation levels and the decreased levels of CAT, GPx, GSH, GST and SOD were restored to the normal levels in a dose-dependent manner when compared with standard drug (Silymarine) treated group.

**Histopathology**
Histological observation of liver tissue of the normal control group animal showed (fig. 6A) hepatic cells with well-preserved cytoplasm, nucleus, nucleolus, and central vein. In rats treated with CCL (fig. 6B), histological observation showed fatty degeneration, damage of parenchymal cells, steatosis and hydropic degeneration of liver tissue. The prominent damage in the central lobular region appeared in the liver. The animals treated with the Et-It (100, 200 and 400 mg/kg) showed an improvement in the pathological changes, reduced the fatty degeneration and inflammation at dose-dependent manner (fig. 6C-E).

DISCUSSION

Prophylactic action in liver damage induced by carbon tetrachloride has widely been used as an indicator of the liver protective activity of drugs in general [18]. Since the changes associated with CCl₄-induced liver damage are similar to that of acute viral hepatitis [19]. Investigation of chronic administration of CCl₄ induced liver damage in animals was chosen as an experimental model.

It is well documented that carbon tetrachloride is biotransformed under the action of cytochrome P-450 system in the microsomal compartment of liver to trichloromethyl or peroxy trichloromethyl free radical. These free radicals bind covalently to the macromolecules and induce peroxidative degradation of the membrane lipids of endoplasmic reticulum rich in polyunsaturated fatty acids. This leads to the formation of lipid peroxides followed by pathological changes such as triacylglycerol accumulation, polyribosomal disaggregating, and depression of protein synthesis, cell membrane breakdown and even death [20].

In general, the extent of liver damage is assessed by histopathological evaluation and serum levels of ALT, AST, ALP, TB and TP release in circulation [21]. When the liver cell plasma membrane is damaged, a variety of enzymes normally located in the cytosol are released into the blood stream. Their estimation in the serum is a useful quantitative marker of the extent and type of hepatocellular damage [22].

In the present study, it was observed that administration of CCl₄ elevates the levels of serum marker enzymes ALT, AST, ALP and total serum bilirubin as well as decreases total serum protein level significantly. Et-It and reference drug silymarin-treated groups exhibited lower serum levels of ALT, AST, ALP and total bilirubin as well as increases total protein as compared to CCl₄ treated groups. The stabilization of serum ALT, AST, ALP, and total bilirubin and the restoration of total protein levels by Et-It is a clear indication of the improvement of the functional status of the liver cells.

Hepatoprotective activity correlated with antioxidant activity since it is free radical mediated damage [23]. An elevated level of malondialdehyde (MDA) reflects an enhanced lipid peroxidation leading to tissue damage and failure of antioxidant defense mechanisms to prevent the formation of excessive free radicals [24]. Treatment with Et-It significantly reversed these changes. Hence it may be possible that the mechanism of hepatoprotection by Et-It is due to its antioxidant effect.

The enzymatic antioxidant defense systems are the natural protector against lipid peroxidation. SOD, CAT and GPx enzymes are important scavengers of superoxide ion and hydrogen peroxide. These enzymes prevent generation of hydroxyl radical and protect the cellular constituents from oxidative damage [25]. In the present study, it was observed that the Et-It significantly increased the hepatic SOD activity in CCl₄ induced liver damage in rats. This shows that the Et-It can reduce reactive free radicals that might lessen oxidative damage to the tissues and improve the activities of the hepatic antioxidant enzyme.

Earlier studies regarding mechanism of CCl₄ induced hepatotoxicity have shown that GSH plays a key role in detoxifying the reactive, toxic metabolites of CCl₄ and that liver necrosis begins when the GSH stores are marked in a depleted state [26]. Administration of the Et-It increased the content of GSH significantly as compared to CCl₄ treated groups.

Catalase (CAT) is an enzymatic antioxidant widely distributed in all animal tissues and the highest activity, is found in the red cells and in the liver. CAT decomposes hydrogen peroxide and protects the tissue from highly reactive hydroxyl radicals [27]. Therefore, the reduction in the activity of these enzymes may result in a number of deleterious effects due to the accumulation of superoxide radicals and hydrogen peroxide. Administration of the Et-It increased the activities of CAT in CCl₄ induced liver damage in rats to prevent the accumulation of excessive free radicals and protected the liver from CCl₄ intoxication.

These findings can be further in corroborated by histopathological studies. The histopathological examination clearly reveals that the hepatic cells, central vein, and portal triad are almost normal in the liver section of rats treated with an Et-It in contrast to the liver section of rats which received CCl₄ only. Thus *Indigofera tirunelvelica* can be considered to be an effective hepatoprotective as it ameliorates almost to normalcy the damage caused by CCl₄ to hepatic function.

It is well established that the phytoconstituent such as Flavonoids, triterpenoids and tannins are well known for their hepatoprotective activities [28]. The literature review revealed that preliminary phytochemical
analysis of heartwood of *Indigofera tirunelvelica* showed the presence of the higher percentage of tannins, flavonoids, triterpenes, saponins, and glycosides reported [29]. The hepatoprotective activity of *Indigofera tirunelvelica* Sanjappaa, may be attributed due to the presence of these constituents. This study supports the traditional claims and the plant *Indigofera tirunelvelica* could be added in traditional preparations for the various liver diseases.

**CONCLUSION**

In conclusion, the present study demonstrated that the Ethanolic extract of *Indigofera tirunelvelica* possesses dose-dependent strong antioxidant activities and significant protective effect against chronic hepatotoxicity induced by CCL₄. The histopathological studies also substantiate the activity of the ethanolic extract of *Indigofera tirunelvelica*. The results suggested that the possible mechanism of this activity may be due to free radical scavenging and antioxidant activity. Therefore, the study scientifically supports the use of this plant in traditional medicine for treatment of liver disorders.
